

Long Questions

1. Explain the principles of pinhole cameras and how they differ from conventional cameras.
2. What are the fundamental concepts of radiometry, and how is light measured in different contexts such as space and on surfaces?
3. Discuss the significance of special cases in radiometry and how they influence our understanding of light propagation.
4. How do different light sources impact radiometric measurements, and what are their effects on surfaces?
5. Describe the concept of shadows and shading in qualitative radiometry and their importance in image interpretation.
6. What factors contribute to local shading in a scene, and how do they affect the perception of depth and form?
7. Explain the concept of photometric stereo and its application in computer vision and image processing.
8. How do interreflections influence global shading models, and what techniques are used to account for them?
9. Discuss the physics of color, including the interaction of light with different surfaces and materials.
10. Explore the mechanisms of human color perception and how it shapes our interpretation of the visual world.
11. Describe various methods for representing color in digital imaging systems and their respective advantages and limitations.
12. Discuss the components of a model for image color and how they contribute to the overall color appearance.
13. How can surface color be inferred from image color data, and what are the challenges involved in this process?
14. Compare and contrast the characteristics of pinhole cameras with those of traditional lens-based cameras.
15. Analyze the implications of different radiometric measurement units in various applications, such as astronomy and remote sensing.
16. Investigate the role of light sources in creating realistic shadows and highlights in computer graphics and rendering.

17. Explore the relationship between surface properties and the way they interact with incident light to produce color.
18. Discuss the psychological and physiological factors that influence human perception of color and its nuances.
19. Evaluate the effectiveness of different color spaces in representing and manipulating color information in digital images.
20. Explain how color models like RGB, CMYK, and HSV are utilized in various applications such as printing and display technologies.
21. Investigate the challenges associated with accurately capturing and reproducing surface colors in digital photography and printing.
22. Compare the advantages and disadvantages of different algorithms used in photometric stereo for estimating surface normals.
23. Discuss the importance of accounting for interreflections in global illumination algorithms for realistic rendering.
24. Analyze the impact of light sources with varying spectral characteristics on the perceived color of objects.
25. Explore the role of texture and material properties in influencing the perceived color of an object under different lighting conditions.
26. Investigate the limitations of traditional pinhole cameras in capturing accurate color information and ways to overcome them.
27. Discuss the challenges involved in accurately measuring and quantifying the radiometric properties of light sources.
28. Evaluate the importance of local shading models in computer graphics for achieving realistic rendering results.
29. Explore the advancements in digital imaging technologies that have led to improved color accuracy and fidelity in images.
30. Analyze how advancements in radiometric measurement techniques have impacted various scientific fields such as environmental monitoring and medical imaging.
31. Explain the fundamental principles of linear filters and their application in image processing.

32. Discuss the concept of convolution in the context of linear filters and its importance in signal processing.
33. Explore the characteristics of shift-invariant linear systems and their relevance in image filtering tasks.
34. How do spatial frequencies relate to image content, and how are they analyzed using Fourier transforms?
35. Explain the concepts of sampling and aliasing in the context of digital image processing and their impact on image quality.
36. Discuss how filters can be used as templates for detecting specific features or patterns in images.
37. Analyze different edge detection techniques and their performance in the presence of noise.
38. Explore methods for estimating derivatives in image processing and their significance in edge detection algorithms.
39. Discuss the challenges involved in accurately detecting edges in images with varying levels of complexity and noise.
40. Explain the concept of texture in images and how it can be represented and analyzed computationally.
41. Discuss the role of oriented pyramids in texture analysis and synthesis, including their advantages and limitations.
42. Explore the application of synthesis by sampling local models in generating realistic textures from sample patches.
43. Analyze the process of shape from texture and how it contributes to 3D scene understanding in computer vision.
44. Compare and contrast different types of linear filters used in image processing, such as Gaussian and Sobel filters.
45. Investigate the mathematical properties of convolution and how they influence the behavior of linear filters.
46. Discuss the trade-offs between spatial and frequency domain representations of images in filter design and analysis.
47. Evaluate the performance of various edge detection algorithms in different scenarios, such as low-contrast images or noisy environments.

48. Explore advanced techniques for edge detection that incorporate machine learning or deep learning approaches.
49. Analyze the role of noise in edge detection algorithms and strategies for mitigating its effects on the final results.
50. Discuss the advantages and limitations of using gradient-based methods for edge detection in digital images.
51. Investigate the challenges associated with texture representation and analysis in non-uniform or irregular textures.
52. Explore the concept of texture synthesis and its applications in computer graphics and image editing.
53. Discuss the importance of scale invariance in texture analysis and synthesis algorithms.
54. Analyze the computational efficiency of different algorithms for texture analysis and synthesis.
55. Explore the role of local and global features in texture analysis and their impact on the quality of synthesized textures.
56. Investigate how shape from texture algorithms can be applied in real-world scenarios such as object recognition or surface inspection.
57. Discuss the challenges associated with texture analysis and synthesis in dynamic or changing environments.
58. Explore the integration of texture analysis with other computer vision tasks such as object detection or scene segmentation.
59. Analyze the relationship between texture features and semantic information in images and their applications in machine learning tasks.
60. Investigate the potential ethical implications of texture analysis and synthesis technologies, particularly in privacy-sensitive applications.
61. Explain the fundamentals of the geometry of multiple views and how it relates to 3D reconstruction from images.
62. Discuss the principles of stereopsis and how the human visual system reconstructs depth perception from binocular disparity.
63. Explore the process of reconstructing 3D scenes from multiple views and the challenges associated with this task.

64. Analyze the role of binocular fusion in the human visual system and its significance in depth perception.
65. Discuss the advantages and limitations of using more cameras for 3D reconstruction compared to using only two views.
66. Investigate the mathematical models and algorithms used in stereopsis for estimating depth from binocular images.
67. Explain the concept of epipolar geometry and its importance in stereo vision and multi-view geometry.
68. Explore the factors that influence the accuracy and precision of depth estimation in stereopsis algorithms.
69. Discuss the challenges associated with calibrating multiple cameras for accurate 3D reconstruction.
70. Analyze the role of occlusions in stereo vision and strategies for handling them in depth estimation algorithms.
71. Investigate how human stereopsis differs from computational approaches to depth perception and reconstruction.
72. Explore the potential applications of stereopsis and multi-view geometry in fields such as robotics, augmented reality, and autonomous vehicles.
73. Discuss the ethical considerations surrounding the use of stereopsis technology, particularly in privacy-sensitive contexts.
74. Analyze the impact of hardware advancements, such as high-resolution cameras and depth sensors, on stereopsis algorithms and applications.
75. Investigate the challenges and opportunities in integrating stereopsis with other computer vision techniques, such as object recognition and tracking.
